## MA 633 - Partition Theory - Lec. 9

- Partitions represented through Ferrers diagrams

Consider the partition:  $8+5+5+4+1+1+1$

Ferrers diagram  
of the partition.

## Conjugate of a partition

6 . . . . .  
5 . . . . .  
3 . . . .  
3 . . .  
2 . .  
2 . .  
1 .

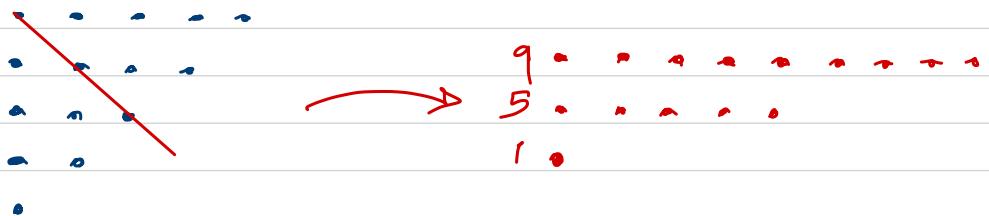

reflecting along the main diagonal gives

7 . . . . . .  
6 . . . . . .  
4 . . . . .  
2 . . . .  
2 . .  
1 .

Conjugate of  
 $(6, 5, 3, 3, 2, 2, 1)$  is  
 $(7, 6, 4, 2, 2, 1)$

Defn. If  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$  is a partition, then the partition  $\lambda' = (\lambda'_1, \lambda'_2, \dots, \lambda'_m)$  by choosing  $\lambda'_i$  to be the number of parts of  $\lambda$  greater than or equal to  $i$  is called the conjugate of  $\lambda$ .

- Thm. The number of self-conjugate partitions of an integer equals the number of partitions of  $n$  into distinct odd parts.

Thm. 13 The number of partitions of  $n$  with at most  $m$  parts equals the number of partitions of  $n$  in which no part exceeds  $m$ .

Proof:

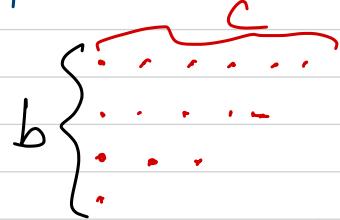

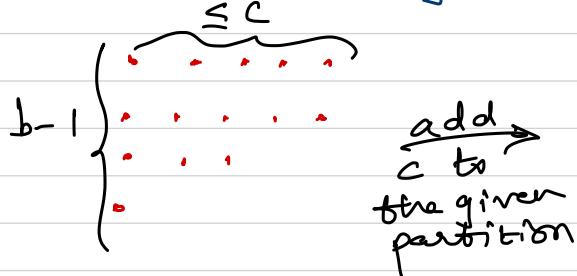

7	•	•	•	•	•	•
7	•	•	•	•	•	•
4	•	•	•	•		
4	•	•	•	•		
1	•					

conjugation

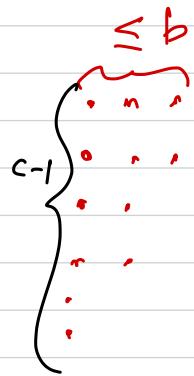

Proof follows from the fact conjugation is a 1-1 correspondence ◻

Thm. 14 The number of partitions of  $a-c$  into exactly  $b-1$  parts, not exceeding  $c$  equals the number of partitions of  $a-b$  into exactly  $c-1$  parts, not exceeding  $b$ ,

Proof: Consider the following partition of  $a-c$  into exactly  $b-1$  parts not exceeding  $c$ ,

number getting partitioned is  $a$ .

Conjugation

number getting partitioned  
is  $a-b$ ,

Since each of the operations (maps) above are bijections we take their composition.

Q.E.D.

Thm. 14 Franklin's proof of Euler's pentagonal number thm.

Let  $p_e(D, n)$  = number of partitions of  $n$  into even number of distinct parts.

Similarly  $p_o(D, n)$ .

$$\text{Then } P_e(D, n) - P_o(D, n) = \begin{cases} (-1)^r, & \text{if } n = \frac{r(3r+1)}{2} \\ 0, & \text{else.} \end{cases}$$

Proof:

We get an "almost" bijection between the sets enumerated by  $P_e(D, n)$  &  $P_o(D, n)$  which fails only when  $n$  is a generalized pentagonal number.

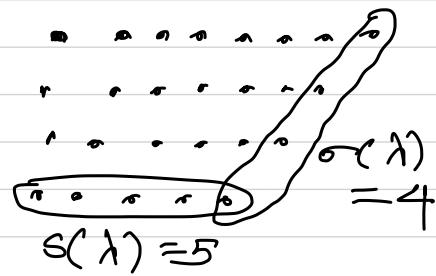

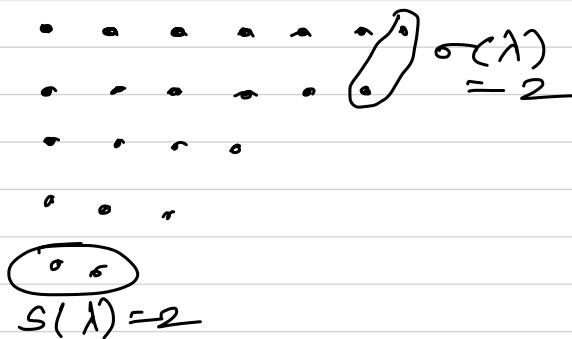

Consider a partition  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_r)$ .

Let  $s(\lambda) = \lambda_r$  (the smallest part of  $\lambda$ ),  
Largest part  $= \lambda_1$ .

$\sigma(\lambda)$  = the number consecutive integers in  
the partition beginning with  $\lambda_1$ .

$$\lambda = (7, 6, 4, 3, 2)$$

$$\lambda = (8 \ 7 \ 6 \ 3)$$

We now transform the partitions as follows:

Case 1:

- (i)  $s(\lambda) \leq \sigma(\lambda)$  : We add one node to each of  $s(\lambda)$  largest parts of  $\lambda$  and delete the smallest part.

$$\lambda = (7, 6, 4, 3, 2)$$

$$\lambda = (8, 7, 4, 3)$$

$$\begin{array}{cccccc} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \end{array} \circ(\lambda) = 2$$

$$\begin{array}{cccccc} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \end{array}$$

$$s(\lambda) = 2$$

### Case 2

(ii)  $s(\lambda) > c(\lambda)$ : In this case, we subtract one node from each of  $c(\lambda)$  largest parts of  $\lambda$  and insert a new smallest part of size  $c(\lambda)$ .

$$\lambda = (8, 7, 4, 3)$$

$$\lambda = (7, 6, 4, 3, 2)$$

$$\begin{array}{cccccc} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \end{array} \circ(\lambda) = 2$$

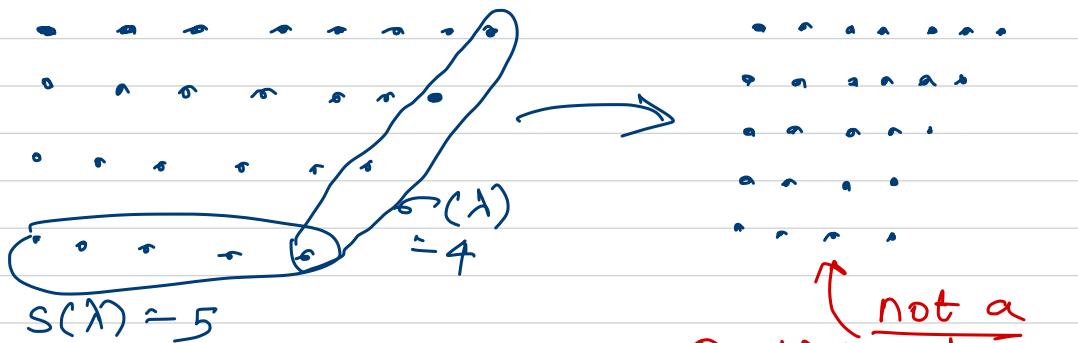

$$\begin{array}{cccccc} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \end{array}$$

$$s(\lambda) = 3$$

These 2 rules change parity of the number of parts of the partition, and note that exactly one case is applicable to any partition  $\lambda$ , it seems as if we have obtained 1-1 correspond.

But it fails for certain partitions.

$$\lambda = (8, 7, 6, 5) \rightarrow (7, 6, 5, 4, 4)$$

This fails precisely when

$$s(\lambda) = r+1, \quad \sigma(\lambda) = r.$$

The number we are partitioning here is

$$(r+1) + (r+2) + (r+3) + \dots + (r+r) \\ = r^2 + \frac{r(r+1)}{2} = \frac{3r^2+r}{2} = \frac{r(3r+1)}{2}.$$
